**ABSTRACT**

The ichthyofaunistic investigation of catchment area of the Parsęta River (N Poland) was made in September and October 1995 and 1996. There were 113 electrofishing sites and 6865 fish representing 21 species were caught. The most common were *Salmo trutta* and *Cottus gobio*. Except some small streams, the ichthyofauna of rivers was poor and dominated by small species and individuals. It seems to be overexploited.
